ABSTRACT: The Institute of Automation and Telemechanics reports the development of a
fiber-optical scanning device. A fiber image distribution scheme and a block diagram
are shown in Figs. 1 and 2. The device is intended for optical scanning of a signal
in the form of a moving dot. The time necessary to scan an n x n element surface is
reduced by a factor of n by virtue of a scanning concept which consists of sequential
scanning of two mutually perpendicular strips 1 element wide and n elements long. The
time necessary to scan one element and one (1 x n) element zone are assumed equal
because of the form of the input signal. The system shown in Fig. 2 includes an opti-
cal part (1) for focusing the image on the fiber matrix, a fiber transformer (2) for
dividing the image into horizontal and vertical zones, two photomultiplier tubes
(FEU-31 type)   (3), control circuits (4), and a scanning mechanism (5) for signal
transfer of zone images to the photomultiplier tube inputs. The image transformer

plier tubes; 4 - control circuits;
5 - scanning mechanism which serially
connects each zone to the photomulti-
plier tube input; 6 - oscilloscope.

consists of glass fibers 20 µ in diameter which are packed into 100 bunches 3 mm in
diameter and 120 mm long and arranged into a 10 x 10 matrix. The other ends of each
fiber cluster are split in two and grouped together as shown in Fig. 1. The operation
of the electronic section is as follows: The control circuit generates a staircase
signal which is allowed to momentarily pass through a gate where a coincidence between
the clock pulse and the signal from the PM tube occurs. Two such circuits are used:
for horizontal and veritcal scanning. To increase the S/N ratio, a special modulating
plate is used. Tests indicate that only 20% of the image screen area causes system-
atic errors proportional to element width. It is stated that this error may be easily
eliminated. Orig. art. has: 5 figures and 2 formulas.   [BD]

TITLE: Investigation into the Mössbauer effect in tin compounds

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 147, no. 1, 1962, 127 - 130

TEXT: The Mössbauer effect in the symmetrical compounds $SnCl_4$, $SnBr_4$, SnI_4, $Sn(C_6H_5)_4$ and SnO_2 and in the asymmetrical compounds Ph_3SnHal ($Ph = C_6H_5$, $Hal = F$, Cl, Br, I) was studied using an apparatus in which the absorber moved uniformly with respect to the source and an apparatus with sinusoidal movement. β-Sn or SnO_2 were used as sources of the 23.8-kev gamma-quanta (Sn^{119m}). With the symmetrical compounds the chemical shift δ of the absorber lines with respect to β-Sn, expressed in mm/sec ($1mm/sec = 7.9 \cdot 10^{-8}$ ev), was a linear function of the electronegativity of the atoms bound to Sn. The equation $\delta = 1.6 \cdot 10^{-29} \left[|\psi_s(0)|^2_{absorb} - |\psi_s(0)|^2_{emitt} \right] \Delta R/R$ ev

Card 1/5

given by A. J. F. Boyle, D. S. P. Bunbury, C. Edwards (Proc. Phys. Soc., 79, 416(1962)) and the data on the ionicity of the Sn-Hal bonds, obtained by the method of A. L. Schawlow (J. Chem. Phys., 22, 1211 (1954)) and those of M. M. Yakshin et al. (ZhNKh, 6, 2425(1961)) on refraction and dielectric constant give $\delta_{ion} = -(5.6 \pm 0.5)$ mm/sec $= -(4.4 \pm 0.4) \cdot 10^{-7}$ ev, $\Delta R/R(Sn^{119}) = +(1.9 \pm 0.2) \cdot 10^{-4}$ for a completely ionized bond. These data enable $|\psi_{5s}(0)|^2$ to be determined directly from δ. In the asymmetrical compounds, asymmetrical doubtlets were observed (Fig. 2) similar to those found by Boyle et al. in SnF_4. The asymmetry was found also in dissolved compounds and cannot be explained by a random orientation of the crystals in the direction of the gamma quanta or by ferromagnetic or paramagnetic impurities. From the equation

$$\frac{\sigma_{13\,полн}}{\sigma_{11\,полн}} = \frac{\int_{-1}^{+1} [2\sqrt{5}\,\overline{P}_0(\cos\vartheta) + \overline{P}_2(\cos\vartheta)]\,f(\cos\vartheta)\,d\cos\vartheta}{\int_{-1}^{+1} [2\sqrt{5}\,\overline{P}_0(\cos\vartheta) - \overline{P}_2(\cos\vartheta)]\,f(\cos\vartheta)\,d\cos\vartheta},\qquad (3)$$

where the subscript полн = total, $\overline{P}_L(\cos\vartheta)$ is the normalized Legendre

Card 2/5

S/020/62/147/001/018/022
B101/B144

polynomial, $f(\cos\vartheta) = \sum a_k \bar{P}_k(\cos\vartheta)$ is the factor determining the intensity of the Mossbauer line, a_k the decay coefficient, it follows that if $\sigma_{13\ tot}/\sigma_{11\ tot} = (2\sqrt{5}a_0 + a_2)/(2\sqrt{5}a_0 - a_2) \neq 1$ (with $a_2 \neq 0$) and $-2\sqrt{5} < a_2/a_0 < 2\sqrt{5}$, each of the peaks of the Mössbauer doublet may become higher than the other one according to the ratio a_0/a_2. This ratio can be determined experimentally. Assuming a quadrupole splitting of the Mossbauer line in SnF_4 and Ph_3SnHal, $q = 6.9 \cdot 10^{18}x$ v/cm^2 is obtained where $q = \partial^2 v/\partial z^2$ is the gradient of the electric field in the region of the Sn^{119} nucleus, and x is the degree of ionization of the bond. For Ph_3SnHal $x \simeq 0.55$ with Hal = I; $x \simeq 0.7$ with Hal = Br, Cl and $x \simeq 1$ with Hal = F. Another possible interpretation of the asymmetrical splitting might be the different hybridization of the sp^3d^2 bonds. In order to explain this problem it is suggested that the effective charges of the halogen and tin atoms be determined directly. When an equimolecular mixture of $SnPh_4$ and SnI_4 was irradiated with 1.6-Mev electrons the Mossbauer spectrum was

Card 3/5

Investigation into the...

S/020/62/147/001/018/022
B101/B144

observed to be greatly changed through the spectra of various disproportionation products $Ph_i SnI_{4-i}$ being superimposed. Hence it is concluded that the Mossbauer effect can be used not only to study the chemical structure but also to solve problems of chemical kinetics and radiation chemistry. There are 2 figures.

AUTHOR: Karyagin, S. V.

TITLE: A possible cause of the asymmetry of the doublet components in the Mössbauer absorption spectrum of some powdery tin compounds

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 148, no. 5, 1963, 1102-1105

TEXT: The asymmetry of the Mössbauer doublet in certain organotin compounds (ZhETF,43,no.2(8),1962; DAN,147,no.1,1962) is explained by an effect of the local electric field components acting on the Sn^{119} nucleus. If the doublet is due to a splitting of the $3/2^{+}$ excited state in the nonuniform electric lattice field, the field acting on the nucleus being, however, axisymmetric, the ratio of the Mössbauer transition intensities will be

$$\frac{I_{\pi}}{I_{\sigma}}=\frac{\int_{0}^{\pi} I_{\pi}(\theta)\, I'(\theta)\sin\theta\, d\theta}{\int_{0}^{\pi} I_{\sigma}(\theta)\, I'(\theta)\sin\theta\, d\theta}, \qquad \begin{array}{l} (\pm^{3}/_{2},\ ^{11}/_{2}^{+}) \rightarrow (\pm^{1}/_{2},\ ^{1}/_{2}^{+}) \\ \hline (\pm^{1}/_{2},\ ^{3}/_{2}^{+}) \rightarrow (\pm^{1}/_{2},\ ^{1}/_{2}^{+}) \end{array}$$

Card 1/4

A possible cause of the asymmetry ...

$I_\pi(\vartheta)$ and $I_\sigma(\vartheta)$ are the total intensities of the Mössbauer and non-Mössbauer transitions for γ-quanta whose angle of incidence is ϑ (measured relative to the crystal axis); $f'(\vartheta)$ characterizes the Mössbauer line intensity. $f'(0)/f'(90^\circ)$ depends on temperature and lattice elastic properties. With

$$I_\pi(\vartheta) = \mathrm{const}\,(1 + \cos^2\vartheta) = \mathrm{const}'[2\sqrt{5}\,\overline{P}_0(\vartheta) + \overline{P}_2(\vartheta)], \qquad (2)$$

$$I_\sigma(\vartheta) = \mathrm{const}\,(\tfrac{5}{3} - \cos^2\vartheta) \doteq \mathrm{const}'\,[2\sqrt{5}\,\overline{P}_0(\vartheta) - \overline{P}_2(\vartheta)],$$

$$\overline{P}_0(\vartheta) = \sqrt{\tfrac{1}{5}}; \quad \overline{P}_2(\vartheta) = \tfrac{1}{2}\sqrt{\tfrac{5}{5}}\,(3\cos^2\vartheta - 1)$$

and $f'(\vartheta) = \sum_k a_k \overline{P}_k(\vartheta)$ one obtains

$$\frac{i_\pi}{i_\sigma} = \frac{1 + a_2/2a_0\sqrt{5}}{1 - a_2/2a_0\sqrt{5}} \qquad\qquad (4).$$

Numerical calculations are carried out for tetragonal symmetry, applying

Card 2/4

A possible cause of the asymmetry ...   S/020/63/148/005/019/029

relations and data from Yu.Kagan (DAN,140,794,1961). If the single
crystal does not exhibit axial symmetry, the $3/2^+$ state splits into two
sublevels which cannot be characterized by the spin projection quantum
numbers. In this case one obtains for the total transition probabilities
to the $\pm$ levels:

$$I_{\pm}(\vartheta, \varphi) = \text{const} \cdot N_{\pm}^2 \left\{ \frac{5}{6} + \frac{\lambda_{\pm}^2}{2} + \left(-\frac{1}{2} + \frac{\lambda_{\pm}^2}{2} \right) \cos^2 \vartheta \pm \lambda_{\pm} \sqrt{\frac{4}{3}} \sin^2 \vartheta \cos^2 \varphi \right\} \quad (12)$$

where

$$N_{\pm} = (1 + \lambda_{\pm}^2)^{-1/2}; \quad \lambda_{\pm} = \frac{\pm s + a}{b}; \quad s = \sqrt{a^2 + b^2}; \quad a = \frac{3}{2} Aeq; \quad b =$$

$$= \frac{\sqrt{3}}{2} Aeq \, \eta; \quad A = \frac{eQ}{2I(2I-1)}; \quad I = \frac{3}{2} \text{ for } \text{Sn}^{119\circ}; \quad eq = \frac{\partial E_z}{\partial z}; \quad \eta =$$

$$= \frac{\partial E_x / \partial x - \partial E_y / \partial y}{\partial E_z / \partial z}; \quad eQ = \langle II | \sum e_i r_i^2 (3 \cos^2 \vartheta_i - 1) | II \rangle$$

II denotes the nuclear quadrupole moment, $\hbar \omega_0^{\pm}$ is the frequency of
the resonance γ-quantum corresponding to an excitation to the $\pm$ level,
ω_0 is the γ-transition frequency without quadrupole field, ϑ, ψ are the
angles of incidence of the γ-quanta absorbed. For $\eta \rightarrow 0$, the plus level

Card 3/4

A possible cause of the asymmetry ...   S/020/63/143/005/019/029
                                           B190/B102

tends to the $(\frac{+3}{-2},\frac{3}{2}^+)$ level and the minus level to $(\pm\frac{1}{2},\frac{3}{2}^+)$ so that the

splitting amounts to 2a and Eq.(12) goes over to (2). Therefore, if
$f'(\nu,\eta)$ = const, then $i_+ = i_-$ and the doublet is symmetrical. Since
i_+/i_- depends on η , the doublet components differ not only in intensity
but also in shape when the local field strength components are scattered.
The doublet asymmetry will thus depend also on temperature, since
$f'(\nu,\eta)$ is a temperature function.

TITLE: Shape of lines of the Messbauer spectrum associated with spread in local
values of the electrical field strength gradient

SOURCE: Fizika tverdogo tela, v. 5, no. 8, 1963, 2128-2132

TOPIC TAGS: Messbauer spectrum, electrical field, gradient, Gamma-transition,
doublet, Bessel function

ABSTRACT: The example of dipole γ-transitions $3^+/2 \rightarrow 1^+/2$ has been used to
compute the shape of the Messbauer spectrum when local values of the electrical
field gradient are spread. If there is no spread, the lines are assumed to be
infinitely narrow; i.e., the other factors tending to expand the lines are not
considered. Two peaks are obtained, and it is shown that these have different
shapes if the Messbauer factor is anisotropic. A formula is found for determining
the degree of spreading of the electrical field gradient from measurement of the
spectrum. When the spread is insufficiently small, the maximums of the spectral
components are displaced relative to the points for energy of γ-quanta, determined

TITLE: Determining the parameters of a localized field from the hyperfine structure of the Mössbauer spectrum

SOURCE: Fizika tverdogo tela, v. 8, no. 2, 1966, 493-499

TOPIC TAGS: Mossbauer spectrum, hyperfine structure, magnetic field, electric field

ABSTRACT: The localized field of a nucleus is described by the parameters $g\beta H$ and e^2Qq and by the angles θ and ϕ (see figure) for orientation of a magnetic field in the system of the principal axes of the tensor for the gradient of the electric field intensity. The authors show that the Brown-Parker method (L. C. Brown, R. M. Parker, *Phys. Rev.*, 100, 1764, 1955) may be used in the case of the $1/2 \rightarrow 3/2$ transition for approximating the parameters e^2Qq, η, θ and ϕ, and for exact determination of $g_{\perp}\beta H$, $g_{\parallel}\beta H$, and

$$ t = \frac{1}{2}\left|e^2Qq\right|\sqrt{1+\frac{1}{3}\eta^2} $$

Card 1/2

L-23155-66
ACC NR: AP6006836   3

as well as for calculating the relative intensities of the components in the hyper-
fine structure in the frequency (relative velocity) spectrum. Various methods are
also proposed for determining the energies of sub-
levels in the hyperfine structure and the chemical
displacement δ. The appropriate formulas are de-
rived. A number of formulas and derivations of a
more general nature may be used for any transitions.
This paper may be of interest to research workers
studying the hyperfine structure which arises in
Mössbauer spectra with simultaneous quadrupole and
magnetic interactions. The author is grateful to
V. I. Gol'danskiy, Ye. F. Makarov and N. D. Sokolov

TITLE: Intensities in the hyperfine structure of Mossbauer absorption spectra

SOURCE: Fizika tverdogo tela, v. 8, no. 6, 1966, 1739-1752

TOPIC TAGS: Mossbauer spectrum, hyperfine structure, line intensity, angular distribution, multipole order, crystal lattice structure

ABSTRACT: In view of the fact that earlier investigations of Mossbauer spectra were made under the assumption that the local field is axially symmetrical and the Mossbauer factor is isotropic, the author derives formulas for the relative intensities in the hyperfine structure and their angular distribution first for an isotropic Mossbauer factor and then with account of the anisotropy. It is assumed first that the nuclei contributing to the spectrum are in identical local fields which have identical orientations relative to the crystallographic axes of the single crystal. In the case of polycrystals, the spectrum is calculated assuming all orientations to be equally probable. The multipole radiation is assumed to be of the mixed EM type. The local field causing the asymmetry is regarded as a superposition of magnetic and quadrupole electric fields. Single crystals with several sublattices, regarded as an intermediate formation between simple single crystals and polycrystals, are discussed.

Card 1/2

L 41583-66

ACC NR: AP6018535

Tables are presented of functions for the calculation of the angular dependences in crystals when the local field is asymmetrical. Typical results of computer calculations of the effect of the anisotropy of the Mossbauer factor are given. It is concluded that the relations derived make it possible to obtain more complete information on crystals than the Mossbauer spectra afford at the present time, but in order for this information to be obtainable it is necessary to increase the accuracy with which the intensities are measured. Orig. art. has: 3 figures, 28 formulas, and 6 tables.

TITLE: Energy distribution in the counterglow spectrum in the region $\lambda\lambda$3900-6500 Å

SOURCE: Astronomicheskiy zhurnal, v. 41, no. 1, 1964, 116-121

TOPIC TAGS: spectrometry, astrophysics, nebular spectrograph, counterglow, counterglow spectrum

ABSTRACT: The spectral investigations of the counterglow, which have been made over the past few years with the aid of the Pariyskiy nebular spectograph, have made it possible to determine several characteristic peculiarities of this phenomenon. Together with the conclusion regarding the absence of any intensification of primary emission lines of the night sky in the region of the counterglow, the presence of a continuous counterglow spectrum has been established. Energy distribution in the counterglow spectrum in the region λ4600-6500 Å was found to be very close to the energy distribution in the zodiacal light spectrum; however, in the 4300-4500 Å region a clearly expressed excess was detected in comparison with the spectrum of zodiacal light. It was also determined that

TITLE: Distribution of Proactinomycetes in sod-podzolic and chernozem soils

SOURCE: AN SSSR. Izvestiya. Seriya biologicheskaya, no. 5, 1965, 772-775

TOPIC TAGS: soil bacteriology, soil type, agriculture science

ABSTRACT: The seasonal dynamics of Proactinomycetes and chernozem soils are stud-
ied. Proactinomycetes in plowed sod-podzolic soil number in the tens and hundreds
of thousands of cells per g of oven-dried soil but they decrease sharply with depth.
In July, when the soil is dry, their numbers decrease considerably and they are vir-
tually nonexistent in the subsoil. The relative percentage of Proactinomycetes
(16%) is highest in unfertilized soil. The predominant forms are *Proact. coralli-
nus* in unfertilized and *Proact. citreus symbioticum* in fertilized soils, respec-
tively. *Proact. mucosum* is abundant in all the soils during the summer. In forest
soils, as in plowed soils, Proactinomycetes populations number in the tens and hun-

Card 1/2   UDC: 576.852

L 15624-66
ACC NR: AP5024154

dreds of thousands per g of oven-dried soil. During the summer months, they de-
crease due to reduction of soil moisture, the minimum being in August when the soil
moisture is lowest. The absolute number of Proactinomycetes is highest in virgin
chernozem soils (millions per g of oven-dried soil in the spring and fall, hundreds
of thousands in the summer), with a sharp decrease downward in the profile. The
species isolated by the authors from chernozem soils included *Proact. corallinus,
Proact. citreus symbioticum, Proact. citreus,* and *Proact. mucosum,* the first two
groups being the most widespread. Orig. art. has: 3 figures, 3 tables.

TITLE: Low-Latitude Aurora of September 29-30, 1957

PERIODICAL: "Izv. Astrofiz. in-ta AN KazSSR", 1959, Vol. 8, pp. 68-78 (Engl. summary)

TEXT: The author describes results of visual and spectrographic observations of aurora of September 29-30, 1957. Observations were conducted near Alma-Ata in the vicinity of the Great Alma-Ata Lake ($43^{\circ}04'$N) at an altitude of about 3,000 m above sea level. Aurora was discovered at $17^{h}13^{m}$ UT on the northern horizon in the form of a very bright redcrimson glow with sharply outlined boundaries. In the initial phase of its development aurora was expanding in altitude and azimuth, and its brightest parts were shifting along the azimuth. At $17^{h}23^{m}$ UT aurora split into 2 parts, almost symmetrical to meridian. At $18^{h}15^{m}$ aurora had the appearance of a diffuse arc. By $19^{h}29^{m}$ UT aurora considerably weakened and was observed up to $22^{h}03^{m}$ UT as a weak glow of various shapes (diffuse spot, dome-like

Low-Latutude Aurora of September 29-30, 1957

arc, wide pillar). Aurora was first of red color but then whitish and greenish
colors began to dominate. The sky brightness in the northern and north-eastern
directions remained enhanced during all the night (till dawn). Spectral observa-
tions of aurora were conducted by means of a speed nebular GAISh spectrograph with
a glass low-dispersion camera. Three regions of the sky were spectrographed simul-
taneously. Observations started still prior to the appearance of aurora. On
spectrograms taken at 16^h36^m and 16^h59^m no anomalies were discovered. In the
spectrum of the sky polar region obtained at 17^h13^m UT red oxygen lines were sharp-
ly enhanced, and their brightness became considerably higher than the brightness
of the green line. The brightness of red lines was growing anomalously strong with
increasing zenith distance. On the spectrogram taken at 17^h31^m the line λ 5200
(NI) was discovered; changes in intensity of lines $\lambda\lambda$ 5200, 5577 and 5893 depend-
ing on the azimuth were noticed. In the violet portion of the spectrum emission
lines $\lambda\lambda$ 4667, 4568, 4410, 4262, 4172, 4074 and 3875 were discovered on the back-
ground of continuous spectrum. After 19^h42^m the regions of zodiacal light and
counterglow were spectrographed. It was found out that prior to dawn in the
zodiacal light region was present the line λ 5200, and the bands of the first
negative system of N_2^+ were enhanced so that their brightness exceeded that of the
green and red lines. The intensity of the red line was close to that of the green

line. No essential changes were detected in the features of the lines $\lambda\lambda 5893$ and 5577. The intensity of emission lines was expressed in absolute units by comparing with stars. The absolute intensity of N_2^+ bands and red lines (OI) was increasing in the period of aurora development. However intensities of lines $\lambda\lambda 5200$, 5577 and 5893 were practically constant.

TITLE: A Spectrophotometrical Investigation of the Aurora at Low Latitudes
               on September 29-30, 1957

PERIODICAL: V sb.: "Spektr. elektrofotometr. i radiolokats. issled. polyarn.
               siyaniy i svecheniya nochnogo neba". No. 2-3. Moscow, AN SSSR, 1960,
               pp. 60-62 (English summary)

TEXT: The author gives an account of the results of determination of the
absolute intensities of the emission lines $[O_{::}]$, NaD, $[NI]$ and the bands of the
first negative system N_2^+ in the auroral spectra observed on September 29-30, 1957,
in the region of the Great Alma-Ata Lake ($40^\circ 04'$ n.lat., $75^\circ 28'$ e.long.). The
observations were carried out with the aid of the nebular spectrograph of ГАИШ
(GAISh). The absolute intensities of emissions were measured on 5 spectrograms
for three points of sky, the spectra of which were obtained with the aid of a
special prismative headpiece which makes it possible to take simultaneously the
photographs of three regions of sky. For the calibration and standardization of

Card 1/2

A Spectrophotometrical Investigation of the Aurora at Low Latitudes on September 29-30, 1957

the spectra, phosphors of constant action were used. The absolute intensities of the lines λ 6,300 + 6,364, 5,893, 5,577, and 5,200 $\mathring{A}$ were determined by gaging them with the phosphor. When deriving the absolute intensities of the emissions, the absorption of the radiation in both prisms and atmosphere was taken into account. In consequence of the low dispersion of the nebular spectrograph, the fine structure of the bands of N_2^+ is not resolved, and the bands λ 4,709 (0.2), 4,652 (1.3), 4,596 (2.4), 4,551 (3.5), 4,278 (0.1), 4,236 (1.2), and 4,200 (2.3)$\mathring{A}$ are obtained as two wide bands with wavelengths of maximum intensity at λ 4,616 and 4,254 $\mathring{A}$. The accuracy of determination of the wavelength amounted to $\pm$ 15 $\mathring{A}$. Basing on the data obtained, it is concluded that the intensity of the bands of N_2^+ considerably increased with time. The intensity of the line λ 6,300 + 6,364 $\mathring{A}$ also increased. Simultaneously, the brightness of the lines λ 5,200 [NI], 5,577 [OI], and 5,893 Na remained practically constant, which is characteristical for the low latitude aurora.

TITLE: The Determination of Temperature of the Upper Atmosphere From
             Rotation Bands of the Hydroxyl Spectrum

PERIODICAL: V sb.: "Spektr., elektrofotometr. i radiolokats. issled. polyarn.
             siyaniy i svecheniya nochnogo neba". No. 2-3, Moscow, AN SSSR, 1960,
             pp. 63-65 (English summary)

TEXT: In accordance with the program of IGY, the temperture of excitation
of OH molecules was determined from the intensity distribution in the rotation
bands (6.1) and (9.3) of the night sky glow spectrum. The observations were
carried out in the vicinity of Alma-Ata at an altitude of 1,400 m. To obtain the
spectra, the diffraction spectrograph CП-48 (SP-48) was used. For standardizing
the spectra, a phosphor of constant action was used. The distribution of energy
in the spectrum in absolute units was obtained by comparison with the phosphor.
For six nights of observations, the intensity was determined of all components of
the bands (6.1) and (9.3) in absolute units, and for two nights of observations

TITLE: The Low-Latitude Aurora Polaris on September 29-30, 1957

PERIODICAL: Izv. Astrofiz. in-ta. AN KazSSR, 1959, Vol. 8, pp. 68-70 (English summary)

TEXT: A bright aurora polaris is described in detail, which was observed on September 29-30, 1957 in the Alma-Ata region; the results of deciphering the aurora spectra are presented. The aurora spectra were obtained by means of a nebular spectrograph with a special prism mount, which made it possible to observe simultaneously three regions of the sky apart by 20^0. The lines λ 6,300-6,364 Å. λ 5,200 Å, and the bands of N_2^+ occur in the spectra. The line λ6,300-6,364 Å is considerably intensified, its intensity attained 300.10^{-5} erg/cm^2sec steradian. The intensity of the N_2^+-band considerably varied during the observations, whereas the intensities of the lines λ 5,200, 5,577, and 5,893 Å were practically constant.

TITLE: The Energy Distribution in the Continuous Spectrum of Zodiacal Light γ

TEXT: Spectrophotometric observations of zodiacal light were made during four nights in the Autumn of 1957 and the energy distribution in the visible spectral region ($\lambda\lambda$ 4100-6600) was obtained. The nebular spectrograph at the State Astronomical Institute imeni P. K. Shternberg was used (focal ratio 1/0.7, dispersion 1500 Å/mm at 5000 Å; Ref.5). It was found that sufficiently strong spectra for the night sky could be obtained with OaF plates (British Kodak) with exposures of 20 to 30 min and slit width 0.3 cm.   The corresponding slit image on the plate was found to be 0.004 cm or 36 Å in the region of H_γ. The spectrograph was set up at an altitude of about 3000 m above sea level and the spectra of zodiacal light and the sky at an angular distance of 20° from its axis were determined simultaneously with the aid of a special attachment incorporating direct vision prisms (Ref.6). The zenith distance was 70° throughout.   Calibration photographs

TITLE: The cometary nature of the Tunguska meteorite

SOURCE: Akademiya nauk SSSR. Komitet po meteoritam. Meteoritika, no. 21, 1961, 32-43.

TEXT: In conducting this study, the authors attempted to support the hypothesis that the Tunguska meteorite was the nucleus of a small comet which formed a tail before colliding with the Earth. Characteristics associated with the approach and explosion of the Tunguska meteorite are discussed and calculated. The estimated initial and final speeds of 60 km/sec and 6 km/sec indicate that the meteorite met the Earth travelling in a direction opposite to that of the Earth and the final mass of the meteorite exploded and was dispersed in the Earth's atmosphere. I.S. Astapovich (Ref.3: Priroda, no.3, 1951, 13-23) made a direct estimate of the explosive force of the meteorite at 10^{23} erg, which the authors find in agreement with their calculation figure. They estimate the change in the geomagnetic field in Irkutsk when the tail of the meteor collided with the Earth at about $3 \cdot 10^{-4}$ gauss, which agrees fairly with the direct observations of K.G. Ivanov [Abstracter's note: see abstract 004 of this set] . The geomagnetic disturbance occasioned by

Card 1/3

The cometary nature ...

32138
S/534/61/000/021/002/005
D055/D114

the meteor resembled an ordinary magnetic storm but was shorter. The size of
the tail of the hypothetical comet was commensurate with that of the Earth,
which accords with the authors' conclusion that the Earth's atmosphere cap-
tured the whole mass of the tail, consisting mainly of dust. The observed
duration of the first phase of disturbance, until the horizontal component
began to fall, was 32 minutes. The corresponding figure, as calculated by the
authors for a hypothetical comet, is 33 mins. This disturbance has a natural
explanation in a collision between the Earth and a comet and could hardly be
connected with the explosion proper of the Tunguska meteorite, as K.G.Ivanov
supposes. The light nights and long, bright sunsets observed in Europe and
Western Siberia after the fall of the meteorite are a further indication that
it was a comet. The phenomenon was not discovered before the collision with
the Earth, because its tail was formed only just before the collision. Refer-
ence is made to the works of I.S.Astapovich, V.G.Fesenkov, B.Yu.Levin(Ref.9:
Fizicheskaya teoriya meteorov i meteornoye veshchestvo v solnechnoy sisteme
[The Physical Theory of Meteors and Meteoric Matter in the Solar System],

TITLE: Hydroxyl emission in the night sky spectrum according
            to observations at Alma-Ata

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 9, 1962, 14-15,
            abstract 9G122 (In collection: Polyarn. siyaniya i
            svecheniye nochn. neba, no. 8, M., AN SSSR, 1962,
            6-8 (summary in Eng.))

TEXT: Observations of the airglow spectrum in the 6200-6600 $\overset{o}{A}$
wavelength region were carried out in the IGY period. The absolute
intensities and rotational temperatures of the OH-bands (6, 1) and
(9, 3) were determined from night sky spectrograms, obtained 'in
the winter and the spring of 1957-1958. The rotational temperature
was ascertained from the P-branch line intensities (transitions
between the levels $2\Pi_{3/2}$). The results of determining the tempera-
ture and total intensities of all the band's components (P, p, Q,

Card 1/2

Hydroxyl emission in ...

S/169/62/000/009/108/120
D228/D307

R) in rayleighs for 18 nights of observation are tabulated. The average rotational temperature ascertained for both bands was found to equal 234°K. No dependence of the OH-band intensity on the rotation temperature was detected either for band (6, 1) or for band (9, 3). The relative population intensity of the 9th and 6th oscillatory levels is independent of the rotational temperature in the range 200 – 250°K. /¯Abstracter's note: Complete translation._/

An-22 transport aircraft, NK-12MB aircraft engine

ABSTRACT: A general description of the new transport aircraft of
An-22 type (also known as "Antey") is presented. Being designed by
O. K. Antonov's Design Office, it is considered the greatest aircraft
in the world. It is equipped with four 15000-hp turboprop engines de-
signed by N. D. Kuznetsov. Two four-blade propellers mounted on coin-
cident axes are driven by each engine. Designed for a takeoff weight
of 250 tons, the aircraft can transport a load of 80 tons over 5000 km.
Its cabin being 4.4 m high, 4.4 m wide and 33 m long is well adapted for
airlift of heavy machinery, vehicles, agricultural products and other
goods to the remotest parts of the country. The operating range of the
aircraft is 11000 km. The aircraft is provided with loading and hoist-

AUTHOR: Karyaki, Yu, Ye.

TITLE: Flow around circular lattices of circles

SOURCE: Leningrad. Politekhnicheskiy institut. Trudy*, no. 230, 1964. Tekhnicheskaya gidromekhanika (Technical hydromechanics), 21-23

TOPIC TAGS: aeromechanics, hydromechanics, hydraulics, flow, flow imposition method, circular lattice

ABSTRACT: The article evolves a complex potential for the flow around a circular lattice of circles using the flow imposition method. This is done, as shown in Fig. 1 of the Enclosure, by arranging lines directed toward the origin of the coordinates, which is the source of flow, along regular lengths at some constant radius. The flow is then integrated:

$$W = \frac{Q}{2\pi}\ln z - i\frac{M}{2\pi R}\ln\frac{R^N e^{-i\lambda V} - z^N}{R^N e^{i\lambda N} - z^N}.$$

Card   1/5

ACCESSION NR: AT4041807

Using polar coordinates a different expression is evolved:

$$\varphi - \frac{M}{2RQ_0} \ln \frac{R^{2N} + r^{2N} - 2R^N r^N \cos N(\lambda + \varphi)}{R^{2N} + r^{2N} - 2R^N r^N \cos N(\lambda - \varphi)} = 0.$$

In this formula N is the number of profiles in the lattice and λ is some angle. This angle may be found by using a similar solution evolved by Blokh for a straight air-foil lattice. This is done by considering that $q = \varphi_0 N/\gamma$ and $\lambda = \varphi_0 \lambda^1$; where $q = 1/t$ - the density of an equivalent straight air-foil lattice and λ' is one of its parameters. Calculations have shown that for a lattice density of $q = \varphi_0 N/\gamma \leqslant 0.92$, the zero flow lines may be approximated by circles with sufficient accuracy. In Fig. 2 of the Enclosure, crosses show the calculated points for a density of $q = 0.606$ ($N = 20$; $R = 1$; $r_2^* = 1.10$); a zero flow line is also shown for comparison where $q = 0.94$ ($N = 20$; $R = 1$; $r_2^* - 1.16$). This allows one to consider that formula (1) expresses the complex potential of radial flow around a circular lattice of circles with sufficient accurary. Orig. art. has: 3 figures and 2 formulas.

KARYAKIN, A.M.

A. M. Karyakin, Major of the Medical Service — Course and Treatment of Peritonitis in Acute Radiation Sickness.

Experiments were performed on 202 animals (rabbits, dogs). Radiation sickness was produced by a total-body single X-irradiation; peritonitis was produced by means of infecting the abdominal cavity with the contents of a large intestine.

The treatment of the peritonitis was conducted with antibiotics (penicillin, streptomycin) in novocaine solution. The antibiotics and the novocaine were injected into the abdominal cavity through a thin elastic rubber drain in a dose of 12,500 units of each antibiotic and 10 cubic centimeters of 0.25 percent novocaine solution per kilogram of weight of the animal for five days three times a day (every eight hours).

Infecting the abdominal cavity with the contents of the large intestine led to the development of a diffuse peritonitis which ended in the death of all the animals of the control groups. The microflora of the peritoneal exudate was polymorphic with a predominance of the colon bacillus.

The early (6 and 12 hours after infection of the abdominal cavity) repeated, intraperitoneal injection of antibiotics with novocaine solution during the initial period of acute radiation sickness led to a considerable reduction in the mortality rate of the animals from peritonitis.

When the antibiotics in novocaine solution were injected into the abdominal cavity for peritonitis the penicillin and streptomycin were found in the blood for the next eight hours. The highest concentration of antibiotics in the blood was found one-half and two hours after the time of their injection. The intraperitoneal injection of antibiotics in novocaine solution exerted a favorable effect on the course of radiation sickness, improving its outcome.

TITLE: Crystallization and structure of vacuum-arc-melted ingots

SOURCE: Stal', no. 9, 1964, 809-812

TOPIC TAGS: steel, ShKh15 steel, steel vacuum arc melting, heat resistant alloy
melting, alloy vacuum arc melting, vacuum arc melting

ABSTRACT: To determine optimal conditions for vacuum-arc melting of steel and
alloys, the crystallization and structure of ShKh15 steel ingots melted in a mold
280 mm in diameter have been studied. It was found that the temperature of the
metal bath surface depends upon the current and can vary from 1540C at 3.3 kamp to
1720C at 5.6 kamp. The excess of heat dissipates rapidly from the surface into a
layer 40—60 mm thick which corresponds to the part of the ingot in contact with
the mold. Therefore, the temperature of the metal bath remains roughly constant.
Only the depth of the bath increases with increased current. In ingots 250—280 mm
in diameter melted with a current of 3—6 kamp, two structural zones were found:
a peripheral zone with fine oriented dendrites and a central zone with large

Card 1/2

L 15737-65
ACCESSION NR: AP4045656

oriented dendrites. The distance between dendrites, the dendritic inhomogeneity, and the content of sulfide and nitride inclusions increase with prolonged crystallization time, i.e. the time during which metal remains in the two-phase region. Nitrides and sulfides are formed as a result of dendritic segregation of impurities (titanium and nitrogen). Formation of various ingot defects is associated with a prolonged duration of the two-phase state which occurs under the effect of a sudden current drop. Dense and uniform steel and alloy ingots are obtained only with a current maintained within certain limits. Melting of ShKh15 steel in a mold 280 mm in diameter should be done with a current of 4 kamp max; melting of a heat-resistant alloy in a mold 380 mm in diameter, with a current of 4.5 kamp max.
